

The first lecture

- this module consists of two pieces of coursework
 - in the first term, [Missile Command/Marble Madness](#) (`CS2S566_CW1_missile.pdf`) implemented in Python and Pygame
 - in the second term, a game implemented in C#
- both pieces of coursework are worth 50%

Python

- Python is a scripting language

Python Gotha's

- blocks are defined by indentation!
- turn off tabs in your favourite editor
- in your own programs examples never create a name clash with a Python library module

Python verses similar tools

- Python is a scripting language
 - it can be compiled if necessary to increase speed
- is more powerful than many other scripting languages, Tcl
 - applicable to larger systems development (games, net admin)
- has a much cleaner syntax than Perl
 - easier to maintain
- does not compete head on with Java
 - Java is a systems language like C++

Python and games

- examples of games which use Python (<http://wiki.python.org/moin/PythonGames>)

Python can be simple

```
#!/usr/bin/python
print "hello world"
```

Python Modules allow for problem decomposition

- similar to Modula-2

```
#!/usr/bin/python
title = "hello world"
```

- above is called `myfile.py`

```
#!/usr/bin/python
import myfile
print myfile.title
```

- when run prints hello world

Alternative import

```
#!/usr/bin/python
from myfile import title
print title
```

- note that all python modules need to be saved as *name.py*
 - so in our example the module `myfile` was saved into a file called `myfile.py`

Python builtin types

- python contains many builtin types
 - use them..
- builtin objects make simple programs easy to understand
 - lists, dictionaries, exist, don't reinvent the wheel
- built in objects are more efficient than custom data types

Builtin objects

- numbers 3.14159, 1234
- strings 'spam', "fred's"
- lists [1, [2, 'three'], 4]
- dictionaries {'food': 'spam', 'taste': 'yum'}
- tuples (1, 'spam', 4, 'U')
- files text=open('/etc/passwd', 'r').read()

Expression operators

- or, and, not logical operators (short circuit)
- <, <=, >, >=, ==, <>, != comparison operators
- x | y bitwise or
- z & y bitsize and
- x << y shift left by y bits
- x >> y shift right by y bits
- x[i] indexing
- x[i:y] slicing
- x.y qualifying (imports)
- x(y) function calls

Strings

- concatenation via +
 - repeated via *

```
#!/usr/bin/python
print "hi " * 4
```

- yields

```
hi hi hi hi
```

Slicing

- given a string, `s= "hello world"`
 - can obtain portion of string via: `s[2:5]`
 - yields: `llo`
- first character has index 0
 - and also -11
 - last character index is 10 in this example
 - last character index is also -1
- negative values start at right and move to the left
- strings can be sliced using positive and negative values

Using dir

- often you may wish to see what methods a module provides
 - run python interactively

```
python
Python 1.5.2
>>> import string
>>> dir(string)
['capitalize', 'capwords', 'center', 'count', \
 'digits', 'expandtabs', 'find', 'hexdigits', \
 'index', 'index_error', 'join', 'joinfields', \
 'letters', 'ljust', 'lower', 'lowercase', \
 'lstrip', 'maketrans', 'octdigits', 'replace', \
 'rfind', 'rindex', 'rjust', 'rstrip', 'split', \
 'splitfields', 'strip', 'swapcase', \
 'upper', 'uppercase', 'whitespace', 'zfill']
```

- displays methods available

Methods and documentation

- [python online docs](http://floppsie.comp.glam.ac.uk/python/html/index.html) `<http://floppsie.comp.glam.ac.uk/python/html/index.html>`
 - under GNU/Linux
- tutorial/laboratory
 - read through the online tutorial under the web address above
 - read about functions and scope rules
 - name resolution, LGB rule
 - local, global, builtin scope

Statements

- assignment, calls, print, if/else/elif, for, while, break/continue
- try, except, raise,
- def, return
 - function definitions and returning values

Statements

- class
- assert
- exec
- del
- global

Example 8 times table

```
#!/usr/bin/python
for n in range(1, 13):
    print n, "x 8 =", n*8
```

Example 8 times table

```
python eight.py
1 x 8 = 8
2 x 8 = 16
3 x 8 = 24
4 x 8 = 32
5 x 8 = 40
6 x 8 = 48
7 x 8 = 56
8 x 8 = 64
9 x 8 = 72
10 x 8 = 80
11 x 8 = 88
12 x 8 = 96
```

Example of for loop

```
#!/usr/bin/python
for n in range(2, 10):
    print 'n is', n
else:
    print 'finished for loop, n is', n
```

Example of for loop

```

./py7.py
n is 2
n is 3
n is 4
n is 5
n is 6
n is 7
n is 8
n is 9
finished for loop, n is 9

```

Tricky example code

```

#!/usr/bin/python
for n in range(2, 10):
    print 'n is', n
    for x in range(2, n):
        print 'x is', x
        if n % x == 0:
            print n, 'equals', x, '*'
            break
    else:
        print n, 'is a prime number'

```

Tricky example code

```

./py6.py
2 is a prime number
3 is a prime number
4 equals 2 * 2
5 is a prime number
6 equals 2 * 3
7 is a prime number
8 equals 2 * 4
9 equals 3 * 3

```

Graphical hello world as an example of Python simplicity

```

#!/usr/bin/python
import Tkinter

def makebutton(message):
    w = Tkinter.Button(text=message, command='exit')
    w.pack()
    w.mainloop()

makebutton("Hello world")

```

Tutorial

- to undertake these tutorials you will need to refer to the [python online docs](http://floppsie.comp.glam.ac.uk/python/html/index.html) (`http://floppsie.comp.glam.ac.uk/python/html/index.html`)

- write a program using a while loop
 - to write out the nine times table

- write a program using a for loop
 - to write out the seven times table

- write a program using a function and if else statement
 - to write out the 3 times table
