Python Pygame: Mario movement

- Mario requires the movement
  - along ramps
  - up ladders
  - up to next ramp and down to lower ramp, when he reaches the end

- ideally he should be able to jump off ladders!
  - left as an exercise for the reader

- Mario also needs the ability to jump
  - left as an exercise for the reader

Python Pygame: Mario movement

- one solution is to put Mario on rails
    - he can change direction (or path at the end of the current path)
    - he can reverse direction at any time
    - he needs the ability to choose a ladder

- placing Mario on rails is just one solution
    - another might be to use sprites for ramps and ladders and detect collisions

Mario on rails

- in Computer Science we often have the tradeoff between complex data structures or complex code

- adding a little complexity to the data structures will reduce the complexity of the code

- define a map for Mario, map is a dictionary of paths
  - at each end point in the Mario diagram we have a path for any chosen direction

Mario on rails

r3r

r3l
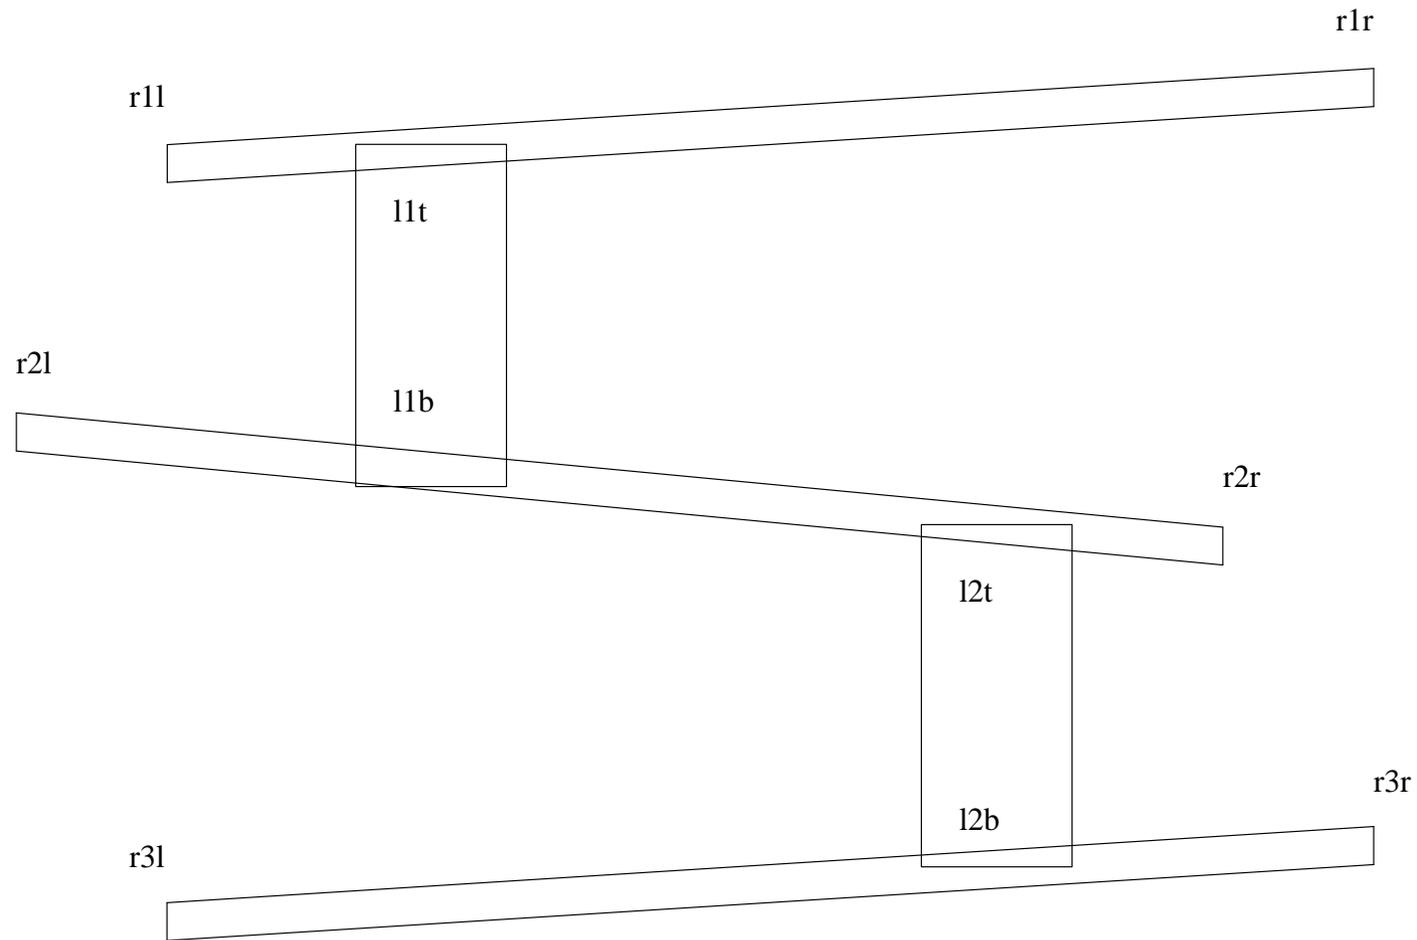

Mario on rails

- starting at `r3l` we note:
  - he cannot move up
  - he can move right towards `r3r` he will pass ladder `l2b`
  - he cannot move down
  - if he moves left he dies

-
```
map = { "r3l-0": None,                # up
        "r3l-1": ["r3r", ["l2b"]], # right
        "r3l-2": None,                # down
        "r3l-3": ["d3", []],       # left
        ...
```

- where
  - `pointname-0` is up, `pointname-1` is right, etc
  - if the path exists it is a list

Mario on rails

- when he reaches `r3r` his choices are:
  - up to ramp 2
  - back to `r3l`

- he cannot go down and he cannot go right

-
```
    "r3r-0": ["r2r", []],      # up
    "r3r-1": None,             # right
    "r3r-2": None,             # down
    "r3r-3": ["r3l", ["l2b"]], # left
```

Path list

- all path lists must be entered into the dictionary `map`
  - however is a path is not an option for Mario then its value in the dictionary is `None`

- any non `None` path will consist of the following entries:
  - first element is the furthest destination way point
  - the second element is also a list of optional ladders

Consider paths for ramp 2

```
    "r2r-0": None,                     # up
    "r2r-1": None,                     # right
    "r2r-2": ["r3r", []],              # down
    "r2r-3": ["r2l", ["l2t", "l1b"]], # left
```

■ he cannot go up or right from point `r2r`

　　■ he can go down to `r3r`

　　■ and he can move left to `r2l` and optionally chose ladders `l2t` or `l1b`

Consider paths for ramp 2

■ and if he reaches point `r2l`

■
```
        "r2l-0": ["r1l", []],               # up
        "r2l-1": ["r2r", ["l2t", "l1b"]],  # right
        "r2l-2": None,                      # down
        "r2l-3": None,                      # left
```

■ here at point `r2l` he can move

  ■ up to `r1l`

  ■ right (and return) to r2r possibly chosing ladders `l2t` and `l1b`

■ he cannot go left or down

Code changes to get basic movement working

■ global variables initialised

■
```
max_speed = 50
step_horizontal = 30
step_vertical = 20
M = None

stand_left, stand_right, jump_left, jump_right, up_left, up_right = range (6)
mario_actions = [stand_left, stand_right, jump_left, jump_right, up_left, up_right]

action_image_names = ["mario-stand-l.png", "mario-stand-r.png",
                      "mario-jump-l.png", "mario-jump-r.png",
                      "mario-up-l.png", "mario-up-r.png"]
```

    while True:
        t = pygame.time.get_ticks()
        if o != t:
            activity_scheduler (t)
            o = t
        checkInput()
        screen.fill(white) # blank the screen.
        draw_polygons ()
        for b in barrels:
            b.update (t)
            screen.blit (b.image, b.rect)
        M.update (t)
        screen.blit (M.image, M.rect)
        pygame.display.flip ()
```

Homework and tutorial

■ finish the path map definition and integrate the movement into your code

■ make Mario jump, fall off ladders

■ improve speed of movement and smoothness/playability

■ scoring, timing, sounds etc

PGE input

■ implementing Mario using the Physics game engine is much easier!

■ since the ball representing Mario is free running it just needs to be given a push when we want it to move

■ we could
- push it left with the left mouse button
- push it right with the right mouse button
- up with the middle mouse button

PGE input

```
def mouse_hit (e):
    global m
    mouse = pge.pyg_to_unit_coord (e.pos)
    if e.button == 1:
        m.put_xvel (gb.get_xvel ()-0.3)
    elif e.button == 3:
        m.put_xvel (gb.get_xvel ()+0.3)
    elif gb.moving_towards (mouse[0], mouse[1]):
        pos = m.get_unit_coord ()
        # print "mouse =", mouse, "ball =", pos
        m.apply_impulse (pge.sub_coord (mouse, pos), 0.4)
    else:
        m.put_yvel (m.get_yvel ()+0.4)
```

PGE input

■ in the main function we register the mouse event with our function

■
```
     pge.register_handler (mouse_hit, [MOUSEBUTTONDOWN])
```

■ please see the implementation of breakout to see how this is integrated into a game breakout example ⟨`http://floppsie.comp.glam.ac.uk/Southwales/gaius/pge/homepage.html`⟩

Collisions in PGE

- refering again to the breakout source code example ⟨`http://`
  `floppsie.comp.glam.ac.uk/Southwales/gaius/pge/`
  `example_games.html`⟩

- notice that the section of code containing `delete_me` and `box_of`

Collisions in PGE

```
def delete_me (o, e):
    global blocks, winner, loser

    blocks.remove (o)
    o.rm ()
    if blocks == []:
        if not loser:
            winner = True
            pge.text (0.2, 0.3, "Winner", white, 100, 1)
            pge.at_time (4.0, finish_game)

def box_of (pos, width, height, color):
    global blocks

    blocks += [pge.box (pos[0], pos[1], width, height, color)\
        .fix ().on_collision (delete_me)]
```

Collisions in PGE

■ the function `box_of` creates a blue box at `pos` with a `width` and `height`

■ it also stipulates that this box is `fixed`

■ furthermore if anything hit this box then the function `delete_me` is called

Collisions in PGE

■ the function `delete_me` is a call back registered by the call to `on_collision` (described on the previous slide)

■ this call back must be defined taking two parameters
- the first, `o`, is the object whose callback is being called
- the second, `e`, is the collision event which has describes the collision

■ by using the event, `e`, it is possible to find out the other object in collision and other properties (if necessary)
