

## PGE and libtool

- examine the file `pge/c/Makefile.am`
  - notice the rule starting with the text
  - `libpgeif.la`: this rule generates the library `libpgeif.la` using a variant of the command given on the previous slides

## More complex example

- passing data from Python into C, C++, Modula-2 shared library
  - can pass `int`, `float`, `double` and `enums` easily enough
- strings are also reasonably well supported
- how do we pass aggregate data types between Python and C/C++?
  - how do we return aggregate from C/C++ into Python?

```

swig -outdir . -o pgeif_wrap.cxx -c++ -python $(top_srcdir)/i/pgeif.i
$(LIBTOOL) --tag=CC --mode=compile g++ -g -c pgeif_wrap.cxx \
-I/usr/include/python$(PYTHON_VERSION) -o pgeif_wrap.lo
gm2 -c -g -I$(SRC_PATH_PIM) -fcpp -fmakelist \
-I$(top_srcdir)/m2 $(top_srcdir)/m2/pgeif.mod
gm2 -c -g -I$(SRC_PATH_PIM) -fcpp -fmakeinit -fshared \
-I$(top_srcdir) $(top_srcdir)/m2/pgeif.mod
$(LIBTOOL) --tag=CC $(AM_LIBTOOLFLAGS) $(LIBTOOLFLAGS) \
--mode=compile gcc -c $(CFLAGS_FOR_TARGET) $(LIBCFLAGS) \
$(libgm2_la_M2FLAGS) $(srcdir)/pgeif.c -o pgeif.lo
$(LIBTOOL) --tag=CC --mode=compile g++ -g -c _m2_pgeif.cpp -o _m2_pgeif.lo
$(LIBTOOL) --tag=CC --mode=link gcc -g -m2_pgeif.lo $(MY_DEPS) \
pgeif_wrap.lo \
-L$(GM2LIBDIR)/lib64 \
-rpath 'pwd' -liso -lgcc -lstc++ -lpth -lc -lm -o libpgeif.la
cp .libs/libpgeif.so ../_pgeif.so
cp pgeif.py ../pgeif.py

```

## Aggregate data types

- an aggregate data type is a data type which contains different sub types
  - for example a struct containing an int and a char field

```
typedef struct aggregate_t {
    int field1;
    char field2;
} aggregate;
```

## Passing aggregate data types from Python into C/C++

- fortunately binary strings of data can be passed between Python and C/C++ using swig
- we can build a sequence of bytes using the Python `struct` module
  - the `struct` module uses a `printf` formatting structure to pack and unpack binary data

## Why do we need to pass aggregate data types from C/C++ to Python?

- consider, `pge`, the shared library module generate events which might be:
  - a draw frame event
  - a collision event
  - a timer event
- the draw frame event
  - contains a list of polygons and circles and their position and colour which need to be rendered to represent the world
  - this is a dynamic list of objects containing many different data types

## Why do we need to pass aggregate data types from C/C++ to Python?

- a collision event
  - contains the time of collision, position of the collision
  - and the object `ids` in collision
- this will be a fixed aggregate structure of known length
- the timer event will have a time field (`double`) and the timer `id` (`integer`) as well as a few other fields
  - this is also fixed in length and represented in C as a `struct`

## Passing aggregate data from C, C++, Modula-2 into Python

- we can use the string passing mechanism to pass bytes
  - the .i file needs extra information to say which functions return binary data **and also that the shared library can set the length**

pge/i/pgeif.i

```
...
#include cstring.i
%cstring_output_allocate_size(char **s, int *slen, );

%{
extern "C" void get_cbuf (char **s, int *slen);
extern "C" void get_ebuf (char **s, int *slen);
extern "C" void get_fbuf (char **s, int *slen);
...
}
```

## Passing aggregate data from C, C++, Modula-2 into Python

- notice that a Python string is created in the shared library and passed back to the Python caller
- also notice that get\_cbuf is a function!
  - returning a string
- the swig information

```
%include cstring.i
%cstring_output_allocate_size(char **s, int *slen, );
```

- indicates these types and name match a return string allocated in the shared library

## Passing aggregate data from C, C++, Modula-2 into Python

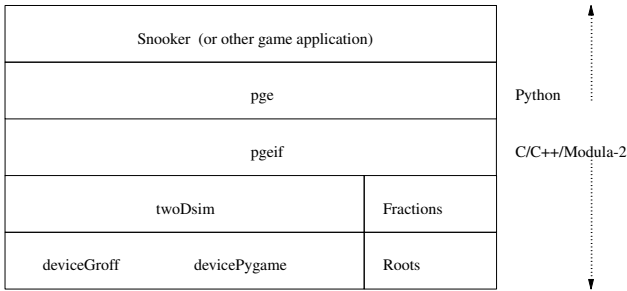

- pge/python/pge.py

```
def runbatch (t):
    if t < 0.0:
        t = 30.0
    _debugf ("runbatch (%f)\n", t)
    pgeif.check_objects ()
    cData = pgeif.get_cbuf ()
    fData = pgeif.get_fbuf ()
    _draw_frame (cData, len (cData), fData, len (fData))
    pgeif.empty_fbuffer ()
    pgeif.empty_cbuffer ()
```

## Passing aggregate data from C, C++, Modula-2 into Python

- swig has many mechanisms to allow binary strings of data to be retrieved
  - above is the safest - as it contains the length

## PGE structure

## Passing aggregate data from C, C++, Modula-2 into Python

- examine the function `_draw_frame` which calls the function

`pge/python/pge.py`

```
#
# _pyg_draw_frame - draws a frame on the pygame display.
#
def _pyg_draw_frame (cdata, clength, fdata, flength):
    global nextFrame, call, _record
```

## Passing aggregate data from C, C++, Modula-2 into Python

`pge/python/pge.py`

```
if _record:
    _begin_record_frame (cdata, clength, fdata, fleng
elif flength > 0:
    _draw_background ()
f = _myfile (cdata + fdata)
while f.left () >= 3:
    header = struct.unpack ("3s", f.read (3))[0]
    header = header[:2]
    if call.has_key (header):
        f = call[header] (f)
    else:
        print "not understood header =", header
        sys.exit (1)
```

## Passing aggregate data from C, C++, Modula-2 into Python

`pge/python/pge.py`

```
if flength > 0:
    _draw_foreground ()
if _record:
    _end_record_frame ()
if flength > 0:
    _doFlipBuffer () # flipping the buffer for an em
    nextFrame += 1
    _debugf ("moving onto frame %d\n", nextFrame)
```

## Inside the shared library

- it creates the byte string containing aggregate data

## Inside the shared library

pge/c/buffers.c

```

/*
 * buffers - wrap the event buffer contents into a binary
 */
extern void deviceIf_getFrameBuffer (void **start,
                                     int *length, int *used);

void get_fbuf (void **start, unsigned int *used)
{
    int length;
    #if !defined (DEBUGGING)
        printf ("calling deviceIf_getFrameBuffer\n");
    #endif
    deviceIf_getFrameBuffer (start, &length, used);
}

```

## Inside the shared library

- examine the file pge/c/deviceIf.c
  - follow the functions:
    - deviceIf\_emptyFbuffer,
    - deviceIf\_useBuffer and
    - deviceIf\_finish
- notice the use of the module MemStream
  - read the documentation of MemStream
    - <http://nongnu.org/gm2/gm2-libs-isomemstream.html>
- MemStream allows the caller to use file operations to maintain a byte string which is contiguous and held in memory

## Conclusion and pgeif.i

- the full API describing the C interface is described in pge/i/pgeif.i
  - examine this file and see how a circle, colour and box are created
- now read the file pge/python/pge.py and see how a call to box and colour is mapped into the pgeif.i calls
