Semaphores and a shared buffer

- recall our previous example from last week which had two processes

    - one process calls `put` and another process calls `get`

- both operate on a shared buffer

    - we use a semaphore called `Mutex` to protect the buffer

Semaphores and a shared buffer

```
void put (char ch)       char get (void)
{                        {

   Wait(Mutex)              Wait(Mutex)
   (* safe to alter *)      (* safe to alter *)
   (* buffer        *)      (* buffer        *)
   place ch into buf        remove ch from buf

   Signal(Mutex)            Signal(Mutex)

                            return ch;
}                        }

     char buffer[Max];  (* global data *)
     SEMAPHORE Mutex;   (* global data *)
```

Semaphores and a shared buffer

- what happens if a process calls `get` before a process calls `put`?

- there is no character to take from the buffer
  - there is no data to return

- what happens if a process keeps calling `put` and no process calls `get`
  - potentially the buffer will be overrun

Semaphores and a shared buffer

- both cases can be fixed by using two additional semaphores

- if there is no character in the buffer and we call `get` then we should *wait* until data arrives

- if there is no space in the buffer and we attempt to `put` a character into the buffer then we should *wait* until space becomes available

Semaphores and a shared buffer

■ we can implement this with two semaphores, which we will declare as

    ■ `itemAvailable`

    ■ `spaceAvailable`

Semaphores and a shared buffer

- before we place a character into a buffer we must
  `wait(spaceAvailable)`

- before we extract a character from a buffer we must
  `wait(itemAvailable)`

- after we place an item into the buffer we must
  `signal(itemAvailable)`

- after we extract an item from the buffer we must
  `signal(spaceAvailable)`

Semaphores and a shared buffer

- what are their initial values for an empty buffer?
  - for simplicity let us assume the buffer can hold four characters
  - `itemAvailable    0`
  - `spaceAvailable   3`

- this buffer mechanism is known as Dijkstra's bounded buffer after its author E.W. Dijkstra who discovered the algorithm in 1960s

Completed implementation of a shared buffer using semaphores

```
void put (char ch)        char get (void)
{                         {
   wait(spaceAvailable)      wait(itemAvailable)
   wait(mutex)               wait(mutex)
   (* safe to alter *)       (* safe to alter *)
   (* buffer        *)       (* buffer        *)
   place ch into buf         remove ch from buf

   signal(mutex)             signal(mutex)
   signal(itemAvailable)     signal(spaceAvailable)
                             return ch;
}                         }

    char buffer[Max];   (* global data *)
    SEMAPHORE mutex;    (* global data *)
```

Completed implementation of a shared buffer using semaphores

- if one process keeps calling `put` and another process calls `get` we see that both processes are synchronising against taking data from an empty buffer and also from putting data into a full buffer

Readers and writers problem and semaphores

■ another common classic problem in operating systems is solving the readers/writers problem

■ here the problem is defined as some common resource needs to be protected such that
  ■ multiple readers can read from the resource simultaneously
  ■ only one writer can write to the resource at a time
  ■ a writer must wait for all readers to finish reading before it can alter the resource

Readers and writers problem and semaphores

- how to solve this with the minimal amount of semaphores?

- this problem is common amoung databases or game servers

- we use a `mutex` semaphore to protect the other data structures used in our lock

- we use another semaphore `writers` to queue multiple writers trying to access the shared resource

- we use an integer count to count the number of readers reading from the resource `readcount`

Readers and writers problem and semaphores

■ the writer processes can be implemented by:

■
```
writers = semaphore (value = 1)

while True:
    ...
    wait(writers)
    # the process can now write to the shared resource
    signal(writers)
    ...
```

Readers and writers problem and semaphores

■ the reader process can be implemented by:

Readers and writers problem and semaphores

```
mutex = semaphore (value = 1)
readcount = 0

while True:
    ...
    wait(mutex)
    readcount = readcount+1
    if readcount == 1:    # first reader waits as a writer
        wait(writers)
    signal(mutex)
    # reader can read the shared resource
    wait(mutex)
    readcount = readcount-1
    if readcount == 0:    # last reader signals as a writer
        signal(writers)
    signal(mutex)
    ...
```

Interprocess communication: Message passing

■ message passing is another form of Interprocess Communication

■ it allows processes to communicate and to synchronise their actions without sharing the same address space

■ a message passing facility provides at least two operations
   ■ `send(message)` and `receive(message)`

■ some message passing libraries allow for variable sized data to be sent/received and other allow a fixed amount of data to be send/received
   ■ tradoffs between complexity of implementation of the library and complexity of the user program

Interprocess communication: Message passing

■ the message passing libraries also may be further complicated by how a process addresses another process

■ consider

■
```
send(P, message)    # send a message to process P
received(Q, message) # receive a message from process Q
```

■ we describe these primitives as having symmetry in addressing
   ■ that is both processes need to know the name of the other to receive and send a message

Interprocess communication: Message passing

■ other library implementations might use asymmetric naming for process addressing, consider:

■
```
send(P, message)       # sends a message to process P
receive(id, message)  # receive a message from any process,
                      # id will contain the processes, name
```

Conclusion

- we have seen how semaphores can be used to solve some classic computer science problems
    - readers/writers and shared buffer

- we have explored the message passing paradigm
